What is GSMS?

- Grocery Store Management System is designed to provide the grocery stores with the benefit of having everything online, from products data to customers data.
- It helps the store managers to perform various functions like checking the products stock, suppliers information, customers information and also allows them to check if a particular product is available in any other branch.
- It also helps to keep track of the store employees.
- Provides a user friendly interface where everything can be accessed with just a button click.

Database

- We have performed various operations like -
  - Create, Insert, Alter
  - Select, Delete, Update

```
-- create database
create database if not exists grocerystore;

-- use database to start performing any operations on the database
use grocerystore;

-- Creating tables Location, designation, employees
create table location( Location_Id varchar(10) not null, Zipcode int not null, City varchar(20) not null,
Street varchar(30) not null, primary key (Location_Id));

insert into location values("JTP01", 413245, "New York", "Jericho"), ("NHP02", 413287, "New York", "Hyde Park"),
("WGP03", 417654, "Pennsylvania", "Willow Grove");
```

- Used "joins" to display data from two different tables at a place.

Database

- Created views using joins to have a virtual table which can be accessed anytime.

```
create view Branch_Manager as select ee.First_Name, ee.Last_Name, loc.Street, loc.City, loc.Zipcode from employees
 as ee inner join location as loc on ee.Dsgn_Id = "M01" and ee.Location_ID = loc.Location_Id;
```

- Created a table for login credentials which allows only the managers of the store to access the database.

GUI - MySQL connection

```
from tkinter import *
from tkinter import ttk
import mysql.connector
import tkinter.messagebox
```

```
conn = mysql.connector.connect(host="localhost", user="root", password="root", database="grocerystore")
mycursor = conn.cursor()
```

Queries from Python

- query = "INSERT INTO location(Location_Id , Zipcode, City , Street) values(%s, %s, %s, %s) "
- values = (Location_Id , Zipcode, City , Street)
- mycursor.execute(query, values)
- conn.commit()

- sql_query = "SELECT * FROM location WHERE Street=%s"
- mycursor.execute(sql_query, name)
- searchResult = mycursor.fetchall()

Limitations & Future Work

- We have developed the GUI using only python Tkinter, so it is not accessible through web. We will be integrating the now python files with web in the future.
- Customer login.
